Ideal gases

Problem 1.- Calculate the RMS speed of nitrogen molecules N_2 of mass $m = 28u$ in a dilute gas (approximate as an ideal gas) at a temperature $T = 1,500K$.

Solution: The average kinetic energy of a molecule in an ideal gas is $\frac{3}{2}k_B T$. This does not take into account rotational or vibrational kinetic energy, only translational. So the average speed (RMS) is found with the equation:

$$\frac{1}{2}mv^2 = \frac{3}{2}k_B T \rightarrow v = \sqrt{\frac{3k_B T}{m}} = \sqrt{\frac{3 \times 1.38 \times 10^{-23} \times 1500}{28 \times 1.66 \times 10^{-27}}} = \mathbf{1,160 \text{ m/s}}$$

Problem 2.- What volume would 105.0 g of NO_2 gas occupy at 31.5 atm and 27.0 °C?

Solution: If NO_2 behaved like an ideal gas, its volume could be calculated as follows:

Molecular mass = $14u + 2 \times 16u = 46u$

Number of moles, $n = \frac{105g}{46g/mole} = 2.28 \text{ moles}$

Temperature, $T = 273 + 27 = 300 \text{ K}$

Pressure, $p = 31.5 \text{ atm} = 31.5 \text{ atm} \left(\frac{1.013 \times 10^5 \text{ Pa}}{1 \text{ atm}} \right) = 3.19 \times 10^6 \text{ Pa}$

So:

$$V = \frac{nRT}{p} = \frac{2.28 \text{ moles} (8.314 \text{ J/Kmole}) (300 \text{ K})}{3.19 \times 10^6 \text{ Pa}} = \mathbf{0.00178 \text{ m}^3}$$

However, NO_2 is not in the gas phase at the conditions given in the problem, so you cannot use the ideal gas equations to calculate its volume.

Problem 3.- Calculate the molecular weight of a gas if its mass is 79.59 g, it is stored in a tank with volume 7.50 L and exerts a pressure of 60.0 atm at a constant temperature of 35.5 °C

Solution: We can calculate the number of moles using the ideal gas law:

$$n = \frac{pV}{RT}$$

$$\text{Pressure, } p = 60.0 \text{ atm} = 60.0 \text{ atm} \left(\frac{1.013 \times 10^5 \text{ Pa}}{1 \text{ atm}} \right) = 6.08 \times 10^6 \text{ Pa}$$

$$\text{Volume, } V = 7.5 \text{ L} = 0.0075 \text{ m}^3$$

$$\text{Temperature, } T = 35.5 + 273.15 = 308.7 \text{ K}$$

$$\text{So, } n = \frac{pV}{RT} = \frac{(6.08 \times 10^6 \text{ Pa})(0.0075 \text{ m}^3)}{8.314 \text{ J/K}(308.7 \text{ K})} = 17.76 \text{ moles}$$

$$\text{The molecular mass is then: } 79.59 \text{ g} / 17.76 = 4.5 \text{ g/mol}$$

Note: This molecular mass is an average. For example, a mixture of helium and neon could have this average molecular mass.

Problem 4.- Determine the mass of neon (atomic mass = 20.18) contained in a 5.25 liter tank at 4.80 atm and 26.85 °C.

Solution: The number of moles is given by:

$$n = \frac{pV}{RT} = \frac{4.8(1.013 \times 10^5 \text{ Pa})(0.0052 \text{ m}^3)}{(8.314 \text{ J / K})(300 \text{ K})} = 1.014 \text{ moles}$$

Since each mole has a mass of 20.18g, the amount of Ne is $1.014 \times 20.18 \text{ g} = \mathbf{20.46 \text{ g}}$

Problem 5.- Glycine is an amino acid and does not behave like an ideal gas, but when in the gas phase and very diluted its behavior can be approximated by the $pV=nRT$ equation. Calculate the density of glycine in the gas phase at $T = 180^\circ\text{C}$ at a pressure of 1.5×10^{-5} torr.

$$1 \text{ atm} = 760 \text{ torr}$$

Solution: The density:

$$\frac{N}{V} = \frac{p}{k_B T} = \frac{(1.5 \times 10^{-5} \text{ torr})(1 \text{ atm} / 760 \text{ torr})(1.013 \times 10^5 \text{ Pa} / 1 \text{ atm})}{(1.38 \times 10^{-23} \text{ J / K})(180 + 273) \text{ K}} = \mathbf{3.20 \times 10^{17} / \text{m}^3}$$

This is in number of molecules per cubic meter.

Problem 6.- 240 J of heat is added to a monatomic ideal gas under conditions of constant volume, resulting in a temperature rise of 12K. How much heat will be required to produce the same temperature change, but at constant pressure?

Solution: The heat capacity at constant pressure is $5/3$ times the heat capacity at constant volume for a monatomic gas, so the heat necessary will be $5/3 \times 240 = \mathbf{400 \text{ J}}$
