## Heat Capacity of Blackbody Radiation

**Problem 1.-** For  $1\text{ m}^3$  of blackbody radiation at room temperature (300K) find

- The heat capacity  $C_V$ ,
- The number of atoms of a monatomic gas that would give the same  $C_V$ .

**Solution:**

a) The energy stored in the electromagnetic waves of a cavity at temperature  $T$  is given by:

$$U = \frac{\pi^2 k_B^4}{15\hbar^3 c^3} VT^4$$

Therefore, the heat capacity will be:

$$C_V = \frac{\partial U}{\partial T} = \frac{4\pi^2 k_B^4}{15\hbar^3 c^3} VT^3$$

Given the volume of  $1\text{ m}^3$  and  $T=300\text{K}$  we get:

$$C_V = \frac{4\pi^2 k_B^4}{15\hbar^3 c^3} VT^3 = \frac{4(3.1416)^2 (1.38 \times 10^{-23} \text{J/K})^4}{15(1.055 \times 10^{-34} \text{Js})^3 (3 \times 10^8 \text{m/s})c^3} (1\text{ m}^3)(300\text{K})^3$$

$$C_V = 8.13 \times 10^{-8} \text{ J/K}$$

Recall that the heat capacity of an ideal gas is  $\frac{3}{2} Nk_B$ , where  $N$  is the number of atoms,

$$\text{so: } \frac{3}{2} Nk_B = 8.13 \times 10^{-8} \rightarrow N = 3.93 \times 10^{15}$$

At standard temperature and pressure, this gas would occupy a volume of  $0.14 \text{ mm}^3$ .

**Problem 2.-** The energy from electromagnetic waves in equilibrium in a box is used to melt ice. If the absolute temperature of the box is increased by a factor of three, the mass of ice that can be melted in a fixed amount of time is increased by a factor of

- 3
- 8
- 27
- 81
- 243

**Solution:** Since the energy is proportional to the temperature to the 4<sup>th</sup> power we can melt  $3^4=81$  times the mass.

**Problem 3.-** Consider a volume of  $1.5\text{ m}^3$  of blackbody radiation at a temperature of  $5800\text{K}$  find the amount of energy in the volume.

**Solution:** recall the Stefan-Boltzmann constant

$$\sigma T^4 = \frac{uc}{4} \rightarrow u = \frac{4\sigma T^4}{c}, \text{ where } u \text{ is the energy density.}$$

Then the energy in  $1.5\text{m}^3$  is

$$\text{Energy} = \frac{4\sigma T^4}{c} \text{Volume} = \frac{4 \times 5.67 \times 10^{-8} \times 5800^4}{3 \times 10^8} \times 1.5 = \mathbf{0.86 \text{ J}}$$

**Problem 4.-** A star has a surface area  $A$  and absolute temperature  $T = 6,000\text{K}$ . You find another star with the same surface area, but it emits 16 times the power of the first one. What is the surface temperature of the second star?

- (A)  $3,000\text{K}$
- (B)  $6,000\text{K}$
- (C)  $12,000\text{K}$
- (D)  $24,000\text{K}$
- (E)  $96,000\text{K}$

**Solution:** (C)
