## Physics II

## Kirchhoff

Problem 1.- Determine the magnitude and direction (up or down) of the current through $\mathrm{R}_{1}$.

Solution: A voltage equation for the outer loop of the circuit looks like this:

The equation is
$18 \mathrm{~V}+(125 \Omega) \mathrm{I}-5.5 \mathrm{~V}=0 \quad$ assuming the current direction is up.
Solving for I we get $\mathbf{- 0 . 1 A}$, where the minus sign indicates that the direction is down.
Problem 2.- We want to find the current through the resistors $R_{1}, R_{2}$ and $R_{3}$. Write down the equations that you need and solve the problem.

Solution: If we assume the currents are in the direction shown in the figure (red arrows) the drop in voltage across the resistors are indicated in blue.

The equations that we need are:
$I_{1}+I_{3}=I_{2}$
$10-3 I_{1}-4 I_{2}=0$
$5-5 I_{3}-4 I_{2}=0$
Which we solve, finding:
$\mathrm{I}_{1}=1.49 \mathrm{~A}$
$\mathrm{I}_{2}=1.38 \mathrm{~A}$
$\mathrm{I}_{3}=\mathbf{- 0 . 1 1} \mathrm{A}$
Here again, the negative sign of $\mathrm{I}_{3}$ indicates that it is in the opposite direction as initially assumed.

Problem 3.- Write down the equations to find the currents in the resistors. The values of the resistances are $R_{l}=10 \Omega, R_{2}=15 \Omega$ and $R_{3}=12 \Omega$.

Solution: We could define three currents going to the right $I_{1}, I_{2}$ and $I_{3}$.
Then the first equation is: $I_{1}+I_{2}+I_{3}=0$
Then we need two loop equations, for example:
$15 \mathrm{~V}-R_{2} I_{2}+R_{3} I_{3}=0$ and
$10 V-R_{1} I_{1}+R_{2} I_{2}=0$
Problem 4.- Find the current through the $125 \Omega$ resistor.

Solution: Following the loop highlighted in the figure we apply Kirchhoff's rules:

$125 I-7-18=0 \rightarrow I=\frac{7+18}{125}=\mathbf{0 . 2} \mathbf{A}$

Problem 5.- Find the current through $\mathrm{R}_{3}$ in the circuit shown:

Solution: There are several ways to solve this problem. Let us look at two of them:
(i) First approach. Let us write the voltage and current equations using Kirchhoff's rules. To do this we first define three currents in our circuit:

With these currents, the voltage on each resistor will be given by Ohm's law, $\mathrm{V}_{1}=\mathrm{R}_{1} \mathrm{I}_{1}, \mathrm{~V}_{2}=$ $\mathrm{R}_{2} \mathrm{I}_{2}$, and $\mathrm{V}_{3}=\mathrm{R}_{3} \mathrm{I}_{3}$.

Recall that the current in a resistor goes from positive to negative, from higher potential to lower potential, so the circuit looks like this:

Now we are ready to write the equations.
Let us look first at the left loop that goes from the source to the resistor $\mathrm{R}_{1}$, resistor $\mathrm{R}_{2}$ and back to the source (loop ABEFA)
$-\mathrm{R}_{1} \mathrm{I}_{1}-\mathrm{R}_{2} \mathrm{I}_{2}+36 \mathrm{~V}=0 \quad$ (Equation 1)
We can write another equation for the voltages in the loop ABCDEFA as follows:
$-\mathrm{R}_{1} \mathrm{I}_{1}-\mathrm{R}_{3} \mathrm{I}_{3}+36 \mathrm{~V}=0 \quad$ (Equation 2)

There is another loop, BCDEB , but we do not gain anything by writing its equation, since it would not be an independent equation. Of course, you can write its equation and use it instead of equation 1 or 2 if you want.

We can write an additional equation for node "B". According to Kirchhoff's rule for current, the net current going to a node should be zero. $\mathrm{I}_{1}$ goes to the node B so we write it with a positive sign. $\mathrm{I}_{2}$ and $\mathrm{I}_{3}$ go away from the node, so we write them with a minus sign in the equation:
$\mathrm{I}_{1}-\mathrm{I}_{2}-\mathrm{I}_{3}=0$
(Equation 3)
We now have three equations and three variables, so the problem is solved from the point of view of physics.

To find $\mathrm{I}_{3}$ we could use any standard method for solving simultaneous equations, for example using determinants, we write the three equations in matrix form:
$\left[\begin{array}{ccc}\mathrm{R}_{1} & \mathrm{R}_{2} & 0 \\ \mathrm{R}_{1} & 0 & \mathrm{R}_{3} \\ 1 & -1 & -1\end{array}\right]\left[\begin{array}{l}\mathrm{I}_{1} \\ \mathrm{I}_{2} \\ \mathrm{I}_{3}\end{array}\right]=\left[\begin{array}{c}36 \\ 36 \\ 0\end{array}\right]$
The determinant of the system is:
$\operatorname{det}\left(\left[\begin{array}{ccc}\mathrm{R}_{1} & \mathrm{R}_{2} & 0 \\ \mathrm{R}_{1} & 0 & \mathrm{R}_{3} \\ 1 & -1 & -1\end{array}\right]\right)=\mathrm{R}_{1} \operatorname{det}\left(\left[\begin{array}{cc}0 & \mathrm{R}_{3} \\ -1 & -1\end{array}\right]\right)-\mathrm{R}_{2} \operatorname{det}\left(\left[\begin{array}{cc}\mathrm{R}_{1} & \mathrm{R}_{3} \\ 1 & -1\end{array}\right]\right)=\mathrm{R}_{1} \mathrm{R}_{3}+\mathrm{R}_{2} \mathrm{R}_{1}+\mathrm{R}_{2} \mathrm{R}_{3}$

And the determinant of $I_{3}$ is:

$$
\operatorname{det}\left(\left[\begin{array}{ccc}
\mathbf{R}_{1} & \mathbf{R}_{2} & 36 \\
\mathbf{R}_{1} & 0 & 36 \\
1 & -1 & 0
\end{array}\right]\right)=\mathrm{R}_{1} \operatorname{det}\left(\left[\begin{array}{cc}
0 & 36 \\
-1 & 0
\end{array}\right]\right)-\mathbf{R}_{2} \operatorname{det}\left(\left[\begin{array}{cc}
\mathrm{R}_{1} & 36 \\
1 & 0
\end{array}\right]\right)+36 \operatorname{det}\left(\left[\begin{array}{cc}
\mathbf{R}_{1} & 0 \\
1 & -1
\end{array}\right]\right)=36 \mathrm{R}_{2}
$$

So $I_{3}$ is:

$$
\mathrm{I}_{3}=\frac{36 \mathrm{R}_{2}}{\mathrm{R}_{1} \mathrm{R}_{3}+\mathrm{R}_{2} \mathrm{R}_{1}+\mathrm{R}_{2} \mathrm{R}_{3}}=\frac{36(12)}{(8)(6)+(12)(8)+(12)(6)}=\mathbf{2 . 0 ~ A}
$$

(ii) Second approach. A somewhat simpler approach would be the following:

Consider resistors $\mathrm{R}_{2}$ and $\mathrm{R}_{3}$, they are in parallel because they share the same voltage. So we can replace them by a single resistor with a value of:

$$
\mathrm{R}_{\text {equivalent }}=\frac{1}{\frac{1}{\mathrm{R}_{2}}+\frac{1}{\mathrm{R}_{3}}}=\frac{1}{\frac{1}{6 \Omega}+\frac{1}{12 \Omega}}=4 \Omega
$$

So the circuit looks like this:

The total current through the circuit is then $I_{\text {Total }}=\frac{36}{R_{1}+4}$
The voltage drop in the resistor $R_{1}$ is then: $V_{R 1}=I_{\text {Total }} R_{1}=\frac{R_{1} 36}{R_{1}+4}$

So, the voltage across the equivalent resistor is $36-V_{R 1}=36-\frac{R_{1} 36}{R_{1}+4}$
Finally, the current through $\mathrm{R}_{3}$ is this voltage divided by $\mathrm{R}_{3}$ :
$I_{3}=\frac{36-\frac{R_{1} 36}{R_{1}+4}}{R_{3}}=\frac{36-\frac{(8)(36)}{8+4}}{6}=\frac{36-24}{6}=\mathbf{2 . 0} \mathrm{A}$

Problem 6.- Find the current through the resistors $\mathrm{R}_{1}, \mathrm{R}_{2}$ and $\mathrm{R}_{3}$.

Solution: Let's assume that the currents are as shown:

The loop equations are:
$10-3 \mathrm{I}_{1}-\left(5 \mathrm{I}_{1}+5 \mathrm{I}_{2}\right)=0$
$-5+4 \mathrm{I}_{2}+\left(5 \mathrm{I}_{1}+5 \mathrm{I}_{2}\right)=0$

And writing them in the standard form:
$-8 \mathrm{I}_{1}-5 \mathrm{I}_{2}=-10$
$5 \mathrm{I}_{1}+9 \mathrm{I}_{2}=5$
The solutions are:

$$
\begin{aligned}
& I_{1}=\frac{\left|\begin{array}{cc}
-10 & -5 \\
5 & 9
\end{array}\right|}{\left|\begin{array}{cc}
-8 & -5 \\
5 & 9
\end{array}\right|}=\frac{-90+25}{-72+25}=\frac{-65}{-47}=\mathbf{1 . 3 8} \mathbf{~ A} \\
& I_{2}=\frac{\left|\begin{array}{cc}
-8 & -10 \\
5 & 5
\end{array}\right|}{\left|\begin{array}{cc}
-8 & -5 \\
5 & 9
\end{array}\right|}=\frac{-40+50}{-72+25}=\frac{10}{-47}=\mathbf{- 0 . 2 1 ~ A} \\
& I_{3}=I_{1}+I_{2}=\mathbf{1 . 1 7} \mathbf{A}
\end{aligned}
$$

Problem 7.- Determine the magnitude and direction (left or right) of the current through $\mathrm{R}_{1}$.

Solution: We concentrate only on the external loop (ABCD) because that makes it easier to find the answer here. If we assume the current goes from left to right through resistor $\mathrm{R}_{1}$ the circuit looks like this:

Recall that when writing Kirchhoff's equations, we should use the correct sign. A good practical rule is that if we come out through the " + " sign when going around the loop we should use a plus in the equation and if it's a "-" sign, then we should use a minus in the equation as well.
The equation is:
$5.5-25 \mathrm{I}_{1}-18=0$
So, the solution is: $\mathrm{I}_{1}=\frac{5.5 \mathrm{~V}-18 \mathrm{~V}}{25 \Omega}=-\mathbf{0 . 5 0} \mathrm{A}$
The minus sign in the answer indicates that the original assumption of the direction of the current was wrong, so the current flows from right to left through resistor $\mathrm{R}_{1}$.

Problem 8.- In the following circuit, determine values of $\mathrm{I}_{\mathrm{ps}}, \mathrm{I}_{1}, \mathrm{I}_{2}, \mathrm{~V}_{\mathrm{A}}$ and $\mathrm{V}_{\mathrm{B}}$.

Solution: Notice that the 3 -ohm resistor is in parallel with the 12 -ohm resistor (they share the same voltage) so they are equivalent to one resistor with a value:
$\mathrm{R}_{\text {equivalent }}=\frac{1}{\frac{1}{3 \Omega}+\frac{1}{12 \Omega}}=2.4 \Omega$
The circuit looks like this:

The current through the power supply can be calculated by applying Ohm's law to the two resistors that are now in series, so:
$\mathrm{I}_{\mathrm{ps}}=\frac{12 \mathrm{~V}}{2.4 \Omega+12 \Omega}=\frac{12 \mathrm{~V}}{14.4 \Omega}=\mathbf{0 . 8 3 3} \mathrm{A}$

With this value of the current we can calculate the voltages:
$\mathrm{V}_{\mathrm{A}}=12 \Omega(0.833 \mathrm{~A})=\mathbf{1 0} \mathrm{V}$
$\mathrm{V}_{\mathrm{B}}=2.4 \Omega(0.833 \mathrm{~A})=\mathbf{2} \mathbf{~ V}$
To determine the currents $I_{1}$ and $I_{2}$ we can use Ohm's law one more time with the value of the voltage $V_{B}$.
$I_{1}=\frac{2 \mathrm{~V}}{12 \Omega}=0.167 \mathrm{~A}$
$I_{2}=\frac{2 \mathrm{~V}}{3 \Omega}=0.666 \mathrm{~A}$
